DIFFERENTIATION OF FOREBRAIN AND HIPPOCAMPAL DOPAMINE 1-CLASS RECEPTORS, D1R AND D5R, IN SPATIAL LEARNING AND MEMORY

Joshua Sariñana,¹ and Susumu Tonegawa¹,²*

ABSTRACT: Activation of prefrontal cortical (PFC), striatal, and hippocampal dopamine 1-class receptors (D1R and D5R) is necessary for normal spatial information processing. Yet the precise role of the D1R versus the D5R in the aforementioned structures, and their specific contribution to the water-maze spatial learning task remains unknown. D1R- and D5R-specific in situ hybridization probes showed that forebrain restricted D1R and D5R KO mice (F-D1R/D5R KO) displayed D1R mRNA deletion in the medial (m)PFC, dorsal and ventral striatum, and the dentate gyrus (DG) of the hippocampus. D5R mRNA deletion was limited to the mPFC, the CA1 and DG hippocampal subregions. F-D1R/D5R KO mice were given water-maze training and displayed subtle spatial latency differences between genotypes and spatial memory deficits during both regular and reversal training. To differentiate forebrain D1R from D5R activation, forebrain restricted D1R KO (F-D1R KO) and D5R KO (F-D5R KO) mice were trained on the water-maze task. F-D1R KO animals exhibited escape latency deficits throughout regular and reversal training as well as spatial memory deficits during reversal training. F-D1R KO mice also showed perseverative behavior during the reversal spatial memory probe test. In contrast, F-D5R KO animals did not present observable deficits on the water-maze task. Because F-D1R KO mice showed water-maze deficits we tested the necessity of hippocampal D1R activation for spatial learning and memory. We trained DG restricted D1R KO (DG-D1R KO) and D5R KO (F-D5R KO) mice on the water-maze task. DG-D1R KO mice did not present detectable spatial memory deficit, but did show subtle deficits during specific days of training. Our data provides evidence that forebrain D5R activation plays a unique role in spatial learning and memory in conjunction with D1R activation. Moreover, these data suggest that mPFC and striatal, but not DG D1R activation are essential for spatial learning and memory. © 2015 Wiley Periodicals, Inc.

INTRODUCTION

The water-maze task is a spatial learning and memory paradigm whereby an animal randomly swims to find a hidden escape platform. Successful water-maze spatial learning requires the hippocampus (Morris et al., 1982). The hippocampus is hypothesized to form an allocentric representation of location whereby external cues provide spatial information regarding position of an escape platform (Eichenbaum et al., 1990; Nakazawa et al., 2002). Relatedly, the dorsal striatum and ventral striatum contribute to spatial processing of early water-maze learning (Annett et al., 1989; Groenewegen et al., 1987; Lee et al., 2014; Woolley et al., 2013). Moreover, the PFC is necessary for water-maze reversal training, which requires extinguishing previous spatial associations and updating newly acquired information into pre-existing spatial schemas (Bartlett, 1932; Lacroix et al., 2002; Piaget, 1926). The hippocampus is also required for updating spatial schemas (Bethus et al., 2010; Dragoi and Tonegawa, 2013; McKenzie et al., 2013; Tse et al., 2007). Although the brain structures required for processing spatial information are well known, the mechanisms underlying spatial learning and memory in these structures remain unclear.

Dopamine 1- and 5-receptor (D1R and D5R) activation is linked to spatial learning and memory processing (Bethus et al., 2010; O’Carroll et al., 2006; Sawaguchi and Goldman-Rakic, 1991; Silva et al., 2012). Constitutive deletion of the D1R significantly impairs regular and reversal learning on the water-maze task (El-Ghundi et al., 1999; Granado et al., 2008; Holmes et al., 2001; Karasinska et al., 2000; Smith et al., 1998). However, constitutive D5R deletion has not shown deficits in water-maze spatial learning and memory (Holmes et al., 2001). Direct injection of D1R/D5R antagonists into the hippocampus impairs regular and reversal water-maze learning, while injection into the striatum impairs water-maze spatial learning and memory (Mele et al., 2004; Silva et al., 2012). However, constitutive KO and pharmacological studies cannot differentiate the specific contribution of region-specific D1R and D5R activation in spatial learning and memory. Constitutive D1R deletion is not region specific, while D1R/D5R antagonists cannot discriminate between D1Rs and D5Rs (Missale et al., 1998). Moreover, the D1R and D5R

Animals

All experiments were carried out on homozygous flx D1R, D5R, or D1R/D5R male mice (C57/BL6 background) that were either positive (KO mice) or negative carriers (flx control mice) of the cre-recombinase transgene. DG-D1R KO animals were trained between 16 and 24 weeks of age, while forebrain animals were between 28 and 40 weeks of age. The original characterization of DG-D1R and F-D1R/D5R KO animals showed that deletion of the D1R or D5R was complete and spatially restricted during the aforementioned ages (Sariñana et al., 2014). Each cage contained two to four mice with ad libitum access to food and water. Experiments and analyses were conducted blind to mouse genotypes. All mice were on a 12-h light/dark cycle. All procedures conformed to the Institutional and NIH guidelines.

Water-Maze Training and Testing

The Morris water-maze task was used to assess spatial learning and memory. All mice were given four training trials per day (45 min intertrial interval) for 10 consecutive days. Mice were given 90 s to find a 12-cm platform submerged in opaque water in a 1.6 m diameter pool. The starting point to find the platform was pseudo-randomized for each training trial. If mice did not find the platform within 90 s, they were placed onto the platform for 15 s. High contrast external cues were prominently displayed on each wall of the training room surrounding the pool. On days 6 and 11, mice received a 60-s probe trial. During the probe, the submerged platform was removed, and the animal was placed into the pool center at the start of the probe. During reversal training and probe trials, the animal received the same protocol as described above. However, during reversal training, the platform was moved to the adjacent quadrant. If a mouse exhibited floating behavior during a single probe trial, they were removed from analysis. If the mouse floated during both probe trials (e.g., reverse probe 1 and 2), they were removed from the study. All water-maze data was collected using Image Water 2020 software.

RESULTS

D1R And D5R Forebrain Expression and Deletion Patterns

Forebrain KO mice were developed by crossing CaMKII-Cre mice (Tsien et al., 1996a) with floxed (flx) D1R/D5R, D1R,
and D5R mice (Sariñana et al., 2014). Using a D1R and D5R specific riboprobe, we show that the D1R mRNA is expressed throughout the dorsal and ventral (V) striatum and mPFC, which consists of the infralimbic (IL), prelimbic (PC), and anterior cingulate cortices (ACC) (Figs. 1A–C). D1R mRNA expression was also observed in the DG of hippocampus, consistent with our previous report (Sariñana et al., 2014) (Supporting Information Fig. 2A).

D1R and D5R deletion in F-D1R/D5R KO animals was quantified (Figs. 1D–F, and Figs. 1O,P). Significant reduction of D1R mRNA in the infralimbic (IL), prelimbic (PC), and anterior cingulate cortices (ACC) (IL/PL—unpaired t test, \( P < 0.05 \); ACC—unpaired t test, \( P < 0.01 \)) was observed in F-D1R/D5R KO DM/ DL, \( n = 6 \); D1R/D5R flx V striatum, \( n = 6 \) and F-D1R/D5R KO V striatum = 3). (J) ACC and V striatum D5R mRNA expression (K) DM and DL striatum D5R mRNA expression. (L) IL/PL D5R mRNA expression in F-D1R/D5R KO mice. (M) ACC and V striatum D5R mRNA expression in F-D1R/D5R KO mice. (O) Quantification of IL/PL and ACC D5R mRNA signal (D1R/D5R flx IL/PL, \( n = 7 \) and F-D1R/D5R KO IL/PL, \( n = 6 \); D1R/D5R flx ACC, \( n = 4 \) and F-D1R/D5R KO ACC = 6). (H) Quantification of DM, DL, and V striatum D1R mRNA signal (D1R/D5R flx DM/DL, \( n = 3 \) and F-D1R/D5R KO DM/DL, \( n = 6 \); D1R/D5R flx V striatum, \( n = 6 \) and F-D1R/D5R KO V striatum = 3). (L) IL/PL D5R mRNA expression. (D) IL/PL D1R mRNA expression in F-D1R/D5R KO mice. (E) ACC and V striatum D1R mRNA expression in F-D1R/D5R KO mice. (F) DM and DL striatum D1R mRNA expression in F-D1R/D5R KO mice. (G) Quantification of IL/PL and ACC D1R mRNA signal (D1R/D5R flx IL/PL, \( n = 5 \) and F-D1R/D5R KO IL/PL, \( n = 5 \); D1R/ D5R flx ACC, \( n = 3 \) and F-D1R/D5R KO ACC = 5). (P) Quantification of DM, DL, and V striatum D5R mRNA signal in F- D1R/D5R KO (D1R/D5R flx DM/DL/V striatum, \( n = 3 \) and F-D1R/D5R KO DM/DL/V striatum, \( n = 3 \)). * denotes \( P < 0.05 \), ** \( P < 0.01 \), *** \( P < 0.001 \), **** \( P < 0.0001 \).

D1R and D5R specific riboprobe, we show that the D1R mRNA is expressed throughout the dorsal and ventral (V) striatum and mPFC, which consists of the infralimbic (IL), prelimbic (PC), and anterior cingulate cortices (ACC) (Figs. 1A–C). D1R mRNA expression was also observed in the DG of hippocampus, consistent with our previous report (Sariñana et al., 2014) (Supporting Information Fig. 2A). D5R mRNA signal was primarily observed in the IL/PL region, with minimal expression in the ACC, and sparse signal throughout the striatum (Figs. 1I–K). D5R mRNA expression was also observed in CA1, CA3, and DG subregions of the hippocampus, consistent with our previous report (Saritana et al., 2014) (Supporting Information Fig. 2C).

D1R and D5R deletion in F-D1R/D5R KO animals was quantified (Figs. 1G,H, and Figs. 1O,P). Significant reduction of D1R mRNA in the infralimbic (IL), prelimbic (PC), and anterior cingulate cortices (ACC) (IL/PL—unpaired t test, \( P < 0.05 \); ACC—unpaired t test, \( P < 0.01 \)) was observed in F-D1R/D5R KO mice (Figs. 1D–F and 1G). Significant deletion was also observed in the dorsal medial (DM), dorsal lateral (DL), and ventral striatum (VS) (DM—unpaired t test, \( P < 0.001 \); DL—unpaired t test, \( P < 0.05 \); VS—unpaired t test, \( P < 0.0001 \)) (Figs. 1D–F and 1H). Consistent with our previous findings, D1R deletion also occurred in the DG of the hippocampus (Sariñana et al., 2014) in KO animals (Supporting Information Fig. 2B). The D5R mRNA signal was significantly reduced in the IL/PL subregions of the mPFC (unpaired t test, \( P < 0.0001 \)) (Figs. 1L,O). Although some reduction of the D5R mRNA signal in the DM striatum seems to occur, there is no significant difference in the D5R mRNA signal between KO and control animals (\( P = 0.2216 \)). There was not significant differences between KO and control animals when comparing DL or V striatum D5R mRNA levels (Figs. 1M,N, and 1P). Consistent with our previous findings, D5R deletion also occurred in the DG and CA1 hippocampal subregions (Supporting Information Fig. 2D) (Sariñana et al., 2014).
Forebrain D1R And D5R Deletion Impairs Spatial Learning and Memory

D1R/D5R flx control and forebrain D1R/D5R KO (F-D1R/D5R KO) animals received water-maze training of four trials per day for 10 consecutive days. During each training trial, mice were given up to 90 seconds to find a submerged and hidden escape platform. F-D1R/D5R KO animals did not show a significant difference in their latency to platform across regular training [two-way ANOVA, \(F_{(1,14)}^{genotype} = 3.846, P = 0.0701\)] (Fig. 2A). However, Bonferroni post test reveals a significant difference between genotypes on day 2 \(P < 0.05\) of water-maze training. When multiple comparisons are not corrected for, using Fishers least significant differences (LSD) post test, a significant difference in latency to platform between genotype was revealed on day 1 \(P = 0.0036\) (Fig. 2A). Memory consolidation during regular water-maze training did not significantly differ between genotypes (unpaired t test, \(P > 0.05\)) (Supporting Information Fig. 1K). On days 6 and 11, the escape platform was removed and mice were given a 60-s spatial memory probe test. During the probe-1 trial, F-D1R/D5R KO animals did not exhibit a significant difference in time spent in the target quadrant as compared with control mice (unpaired t test, \(P > 0.05\)) (Figs. 2B–D). In contrast, F-D1R/D5R KO mice exhibited a significant difference in time spent in the target quadrant during the probe-2 trial \(P < 0.05\) (Figs. 2E–G). To test the animal’s ability to extinguish the original platform location and update new spatial information into a pre-existing spatial schema, mice were given reversal training (Fig. 2H). In reversal training, the escape platform was moved to the opposite quadrant and mice were given the same training schedule as during regular training. The latency curves during reversal training did not significantly differ between F-D1R/D5R KO animals and control mice [two-way ANOVA, \(F_{(9,126)}^{Interaction} = 0.6857, P = 0.7208\)] (Fig. 2H). Bonferroni post test did not reveal a significant difference between genotypes on any single training day. Using Fishers LSD post test, we found that F-D1R/D5R KO animals were significantly slower to reach the platform on days 2 \(P < 0.0279\) and 3 \(P < 0.0195\) in comparison to control mice during reversal training (Fig. 2H). Memory consolidation during reversal training was not significantly different between F-D1R/D5R KO and control animals (unpaired t test, \(P >

Hippocampus
KO and control animals did not significantly differ in time spent in the target quadrant (unpaired t test, $P > 0.05$) during reversal probe-1 (Figs. 2I–K). On the second reversal probe trial, F-D1R/D5R KO mice spent significantly less time in the target quadrant compared with control mice (unpaired t test, $P < 0.05$) (Figs. 2L–N). F-D1R KO animals displayed similar swim speed during probe-1 (unpaired t test, $P > 0.05$), but enhanced swim speeds during probe-2 in comparison with flx control animals (unpaired t test, $P < 0.05$) (Supporting Information Fig. 1L). Swim speeds did not significantly differ in F-D1R/D5R KO mice for reversal probes-1 and 2 (probe-1—unpaired t test; $P > 0.05$; probe-2—unpaired t test; $P > 0.05$) (Supporting Information Fig. 4L). No significant differences were found between F-D1R/D5R KO animals and control mice in thigmotaxis during regular and reversal spatial memory probes (Supporting Information Figs. 1J and 4J). The rotarod task is an important behavioral protocol to test gross motor ability in rodents (Crawley, 1999). Gross motor impairments could affect swimming ability during water-maze training. We previously reported that F-D1R/D5R KO mice did not show impaired motor behavior as measured on the rotarod task (Sariñana et al., 2014).
animals also displayed consolidation deficits during reversal training (unpaired $t$ test, $P < 0.05$) (Supporting Information Fig. 4E) as compared with controls. During reversal spatial memory probe-1 (Figs. 3I–K), F-D1R KO mice displayed perseverative behaviors as shown by their increased return to the original platform location during regular water-maze training (unpaired $t$ test, $P < 0.05$) (Fig. 3I, inset). On the reversal probe-2 trial, D1R-KO mice showed significant deficits in spatial memory performance as compared with control animals (unpaired $t$ test, $P < 0.05$) (Fig. 3L–N).

The striatum is essential for the development of motor skills (Jueptner et al., 1997). F-D1R KO mice showed no difference in swim speed during probe-1 (unpaired $t$ test; $P > 0.05$) and probe-2 trials (unpaired $t$ test; $P > 0.05$) (Supporting Information Fig. 1F). Similarly, F-D1R KO animals did not show a significant difference in swim speed during reversal trials (unpaired $t$ test; $P > 0.05$) (Supporting Information Fig. 4F). F-D1R KO animals mice did not significantly differ in thigmotaxis behavior during probe-1 (unpaired $t$ test, $P > 0.05$), but significantly reduced levels of thigmotaxis during probe-2 (unpaired $t$ test, $P < 0.05$) (Supporting Information Fig. 1D). During reversal probes, F-D1R KO animals did not show significant differences in thigmotaxis during probe-1 (unpaired $t$ test, $P > 0.05$) but significant reduction during probe-2 (unpaired $t$ test, $< 0.01$) (Supporting Information Fig. 4D). F-D1R KO animals did not significantly differ in total distance traveled in the open field task when compared with control mice [two-way ANOVA, $F_{(1,14)}^{(genotype)} = 2.836$, $P = 0.1143$] (Supporting Information Fig. 3A). Moreover, F-D1R KO present similar motor activity on the rotarod task in comparison to flx control animals [two-way ANOVA, $F_{(1,14)}^{(genotype)} = 0.2266$, $P = 0.6414$] (Supporting Information Fig. 3C).

**Forebrain D5R Deletion Does not Result in Observable Spatial Learning and Memory Deficits**

F-D5R KO mice did not significantly differ in latency during training [two-way ANOVA, $F_{(1,17)}^{(genotype)} = 2.495$, $P = 0.1326$] (Fig. 4A), memory consolidation (unpaired $t$ test, $P > 0.05$) (Supporting Information Fig. 1H), and time spent in the target quadrant during the spatial memory probe trials as compared with flx controls (probe-1 and -2, unpaired $t$ test, $P > 0.05$) (Figs. 4B–D and 4E–G). F-D5R KO mice did not exhibit observable deficits in reversal escape latency [two-way ANOVA, $F_{(1,16)}^{(genotype)} = 0.05639$, $P = 0.8153$] (Fig. 4H) or memory consolidation (unpaired $t$ test, $P > 0.05$) (Supporting Information Fig. 4H) during reversal training.
DG D1R KO mice did not significantly differ in total distance traveled in the open field task when compared with control mice [two-way ANOVA, $F_{(1,30)}^{\text{genotype}} = 0.7745, P = 0.3935$] (Supporting Information Fig. 3B). F-D5R KO animals did not present significant differences in motor activity on the rotarod task [two-way ANOVA, $F_{(1,14)}^{\text{genotype}} = 1.013, P = 0.3313$] (Supporting Information Fig. 3D).

**DG D1R Deletion Does not Impair Spatial Memory**

We recently reported on the generation and characterization of a DG-restricted D1R KO mouse line (DG-D1R KO). We showed that D1Rs are primarily expressed in the DG of the hippocampus. In order to spatially restrict and isolate D1R function in hippocampal-dependent spatial learning and memory, we trained DG-D1R KO mice on the water-maze task. Control D1R flx and DG-D1R KO mice Control and DG-D1R KOs exhibited similar escape latencies during training [two-way ANOVA, $F_{(1,29)}^{\text{genotype}} = 2.896, P = 0.0995$] (Fig. 5A). Bonferroni post test did not reveal a difference between genotypes on any single day during training. However, a Fisher’s LSD post test revealed significant differences on days 5 ($t$ test, $P < 0.05$) and 7 ($t$ test, $P < 0.05$) (Fig. 5A). Memory consolidation during regular training was similar between DG-D1R KO animals and control mice (Supporting Information Fig. 1B). There was no difference between control and DG-D1R KO mice on the time spent in the target quadrant on probe-1 ($t$ test, $P > 0.05$) and on probe-2 ($t$ test, $P > 0.05$) (Figs. 5B–D and 5E–G). We observed no significant difference between control D1R flx and DG-D1R KO mice on reversal training latency [two-way ANOVA, $F_{(1,14)}^{\text{genotype}} = 1.013, P = 0.3313$] (Supporting Information Fig. 3D).
ANOVA, $F_{(1,29)}^{genotype} = 2.103, P = 0.1578$] (Fig. 5H). Bonferroni post test did not reveal significant differences between genotypes on any single day of training. However, Fisher’s LSD post test revealed significant differences between DG-D1R KO and flx controls on day 8 (unpaired $t$ test, $P < 0.05$) (Fig. 5H). Memory consolidation was similar between DG-D1R KO animals and control mice (Supporting Information Fig. 4B).

Time spent in the target quadrant during reversal probe-1 (unpaired $t$ test, $P > 0.05$) (Figs. 5I–K) and 2 (unpaired $t$ test, $P > 0.05$) (Figs. 5L–N) were not significantly different between genotypes. Both flx and DG-D1R KO animals displayed similar time spent using non-spatial strategies to search for the escape platform, that is, thigmotaxis (Supporting Information Fig. 1A).

DG-D1R KO mice showed no significant differences in swim speed during probe-1 (unpaired $t$ test, $P > 0.05$) and probe-2 trials (unpaired $t$ test, $P > 0.05$) (Supporting Information Fig. 1C). During reversal probes-1 and 2 DG-D1R KO animals did not show a significant difference in swim speed (probe-1 and 2, unpaired $t$ test, $P > 0.05$) (Supporting Information Fig. 4C). DG-D1R KO animals did not show a significant difference in thigmotaxis during regular and reversal probes (probe-1 and 2, unpaired $t$ test, $P > 0.05$), reversal probe-1 and 2, unpaired $t$ test, $P > 0.05$) (Supporting Information Figs. 1A and 4A). We previously reported that DG-D1R KO mice did exhibit significant impairment in motor behavior as measured on the rotarod task or significant differences traveled in the open field task (Sariñana et al., 2014).

**DISCUSSION**

In this study, we found that forebrain D1R, but not D5R, activation is crucial for spatial learning and memory, and DG D1Rs are not necessary for spatial memory. Our in situ data shows that forebrain D1R mRNA signal is reduced in the IL/PL, ACC, and MD, ML, and V striatum in F-D1R/D5R KO mice (Figs. 1D–H). In contrast, the D5R mRNA signal was significantly reduced only in the IL/PL region (Figs. 1L,O). During water-maze training, F-D1R/D5R KO animals showed slight deficits in latency to platform during regular and reversal learning (Figs. 2A,H). Still, F-D1R/D5R KO mice reach the same criterion as their flx control counterparts. F-D1R/D5R KO animals showed spatial memory deficits during both regular and reversal training (Figs. 2E,L). To differentiate the contribution of forebrain D1R from D5R activation in spatial learning and memory processing, we utilized forebrain restricted D1R and D5R KO animals. F-D1R KO mice displayed deficits in spatial learning and memory. Specifically, F-D1R KO animals showed deficits in escape latency during regular water-maze training (Fig. 3A). However, F-D1R KO animals learned the spatial location of the escape platform well enough to show spatial memory that’s similar to that of flx control animals (Figs. 3B,E). In contrast, F-D1R KO mice presented greater latency deficits during reversal training (Fig. 3H), as well as deficits in memory consolidation (Supporting Information Fig. 4E) and spatial memory (Fig. 3L). Moreover, during reversal probe-1, F-D1R KOs swam back to the original water-maze platform location significantly more than the control animals, suggesting deficits in extinguishing the prior platform location (Fig. 3L, inset). Although F-D5R KO animals did not exhibit any observable deficits in spatial learning and memory (Fig. 4 and Table 1), double F-D1R/D5R KO mice presented deficits that differed from F-D1R KOs. Moreover, unlike F-D1R KO mice, F-D1R/D5R KO animals were able to extinguish the prior escape platform location to update the former spatial schema learned during regular water-maze training. Unexpectedly, DG-D1R KO mice only showed a slight impairment during water-maze regular and reversal training, but no significant difference in spatial memory performance in comparison to control mice (Fig. 5 and Table 1). Taken
together, our data shows for the first time that forebrain D5R activation must contribute to spatial information processing. We also demonstrate that mPFC and striatal, but not DG, D1Rs are essential for spatial learning and memory.

**Dentate Gyrus D1Rs are not Required for the Morris-Water Maze Task**

It is well established that the hippocampus is necessary for spatial learning and memory (Eichenbaum et al., 1990; Morris et al., 1982; Tsien et al., 1996b). D1R/D5R antagonists infusion into the hippocampus results in water-maze deficits (Silva et al., 2012) as does constitutive D1R deletion (Granado et al., 2008). However, constitutive D5R deletion does not impair spatial learning and memory (Holmes et al., 2001) and our data shows that F-D5R KO animals do not exhibit significant changes in spatial learning and memory (Fig. 4). Thus, D1Rs, but not D5Rs, are necessary for spatial learning and memory. However, D1R/D5R antagonists block norepinephrine and serotonergic receptors (5HT-2), the serotonin transporter, which expresses throughout the hippocampus, and other g-protein coupled receptors. Hicks et al., 1984; Ohlstein and Berko-witz, 1985; Fink et al., 2007; Zarrindast et al., 2011), obscuring a strong conclusion as to whether hippocampal D1R activation is truly required for spatial learning and memory. Our data, shows that the D1R primarily expresses in the DG of the hippocampus, but not CA3 or CA1 (Supporting Information Fig. 2), which is in agreement with previous findings (Freemue et al., 1991; Mansour et al., 1992; Mu et al., 2011; Sariñana et al., 2014) However, a recent publication suggest that there is sparse D1R expression in the CA3 and CA1 hippocampal subfields, particularly in interneurons (Gangarossa et al., 2012). Based on the evidence above, we conclude that DG D1Rs are not required for spatial memory as assayed by our water-maze task. Further research studying sparse D1R expression throughout the hippocampus is required to further understand the role of hippocampal D1R activation on spatial learning and memory.

**PFC D1R and D5R Activation Work in Conjunction for Spatial Memory Updating**

Although D5R expression occurs throughout all hippocampal subregions, constitutive D5R KOs and forebrain wide D5R deletion does not appear to significantly affect spatial learning and memory (Holmes et al., 2001) (Fig. 4). D5Rs may not be required for spatial learning and memory, but D5R activation could still be important for spatial memory updating. D1R and D5R mRNA co-express in the IL/PL cortex (Figs. 1A, I) and both F-D1R and F-D5R animals display significant receptor deletion of D1Rs and D5Rs, respectively, in the IL/PL cortex. F-D1R KO animals differ in phenotype in comparison to F-D1R/D5RKO animals, which suggests that D5R activation affects spatial learning and memory processing. More specifically, F-D1R KO animals display perseverative behaviors (Fig. 3l, insert), while F-D1R/D5R KO mice do not. Given the importance of the PFC in reversal learning (Lacroix et al., 2002), it is feasible that D5R deletion in the IL/PL cortex results in the phenotypic difference between F-D1R and F-D1R/D5R KO mice with regard to perseverative behaviors. A possible explanation for the observed differences between F-D1R/D5R KO and F-D1R KO animals is that D1R and D5R activation results in downstream processing that impairs neuronal computational power. For example, the D1R directly couples to the GluN1 and GluN2A subunits of the n-methyl-D-aspartate receptor (NMDAR) and modulates the NMDAR ionomic currents (Lee et al., 2002; Pei et al., 2004). Similarly, the D5R directly couples to the γ2 subunit of the γ-aminobutyric acid subtype-A receptor (GABAAR), modulating the inhibitory current (Liu et al., 2000). Given the differences in D1R and D5R protein coupling, D1R would likely express at excitatory synapses, while D5R expression would receive inhibitory inputs along the dendritic shafts (Megias et al., 2001; Wierenga et al., 2008). A difference in D1R and D5R distribution would support enhanced computational power of single neurons to maximize memory processing and storage (Govindarajan et al., 2006, 2011). Thus, deletion of the D1R or D1R and D5R could significantly alter neuronal computation leading to the observed differences in perseverative behavior in F-D1R KO and F-D1R/D5R KO animals. The difference in spatial learning and memory phenotypes between F-D1R/D5R KO and F-D1R KO mice shows that forebrain D5R activation is certainly contributing to spatial information processing.

**Striatal D1R Contribution to Spatial Processing**

Lesions to either the dorsal medial or ventral striatum significantly impair early water-maze training and spatial memory (Annett et al., 1989; Devan and White, 1999). The DM striatum has been shown to process spatial information, while the DL striatum is associated with procedural learning (Voorn et al., 2004). We observed a strong deletion in the ventral striatum, which links spatial information to reinforcing events (van der Meer and Redish, 2011). The strong deletion of the D1R in the DM and ventral striatum in the D1R-KO and D1R/D5R KO animals suggests that spatial information would be impaired, while weaker deletion in the DL striatum suggests impairments in procedural learning. Given the spatial memory deficits observed in F-D1R KO and F-D1R/D5R KO, but not DG-D1R KOs, suggests that D1R deletion in the DM and ventral striatum underlies the observed spatial memory deficits (Figs. 2E,L, and Fig. 3L). However the deletion of D1Rs in the DL striatum might underlie the deficits observed during spatial learning in F-D1R KO and F-D1R/D5R KO animals given that procedural nature of water-maze training (Figs. 2A,H and Fig. 3A,H). Yet neither F-D1R KO nor F-D1R/D5R KO animals exhibit gross motor deficits as measured on the rotarod task, suggesting that general motor activity does not underlie the deficits observed during water-maze training. DG-D1R KO animals also show subtle deficits during water-maze training, which suggests that DG D1R activation could also contribute to the spatial component during water-maze training.

Hippocampus
The genetic tools used in our current study have provided a unique advantage over pharmacological and global KO studies by distinguishing the D1R from the D5R with gene-specific and spatially restricted KOs. Our finding that the primary site of D1R expression is the DG, and not CA1, is consistent with some previous findings (Fremaux et al., 1991; Mansour et al., 1992; Mu et al., 2011). However, other previous studies have focused on hippocampal CA1 D1R activation as the driver of synaptic plasticity, learning, and memory (Huang and Kandel, 1995; Lemon and Manahan-Vaughan, 2006; Li et al., 2003; Ortiz et al., 2010; Smith et al., 1998). Some of these previous studies attributed the observed deficits to CA1 D1Rs, which may be due to sparse expression of CA1 D1Rs (Gangarossa et al., 2012). Still, deficits presumed to be due to CA1 D1Rs may instead be due to disruption of D5R function. Therefore, future research on D1R versus D5R function in hippocampal memory processing as well as physiological changes within the hippocampus should be studied utilizing genetic tools given the limitations of current pharmacological reagents.

Acknowledgment

The authors thank Derek Buhl for water-maze heat-map scripts for analysis, Julie Moyer, Lisa Sultzman, Wenjiang Yu for experimental support, and Takashi Kitamura for comments on the manuscript.
